**Roland Rau**  
@Demographie

CRAN Task View: Survival Analysis

**Maintainer:** Arthur Allignol, Aurelien Latouche  
**Contact:** arthur.allignol at gmail.com  
**Version:** 2022-03-07  
**URL:** <https://CRAN.R-project.org/view=Survival>  
**Source:** <https://github.com/cran-task-views/Survival/>

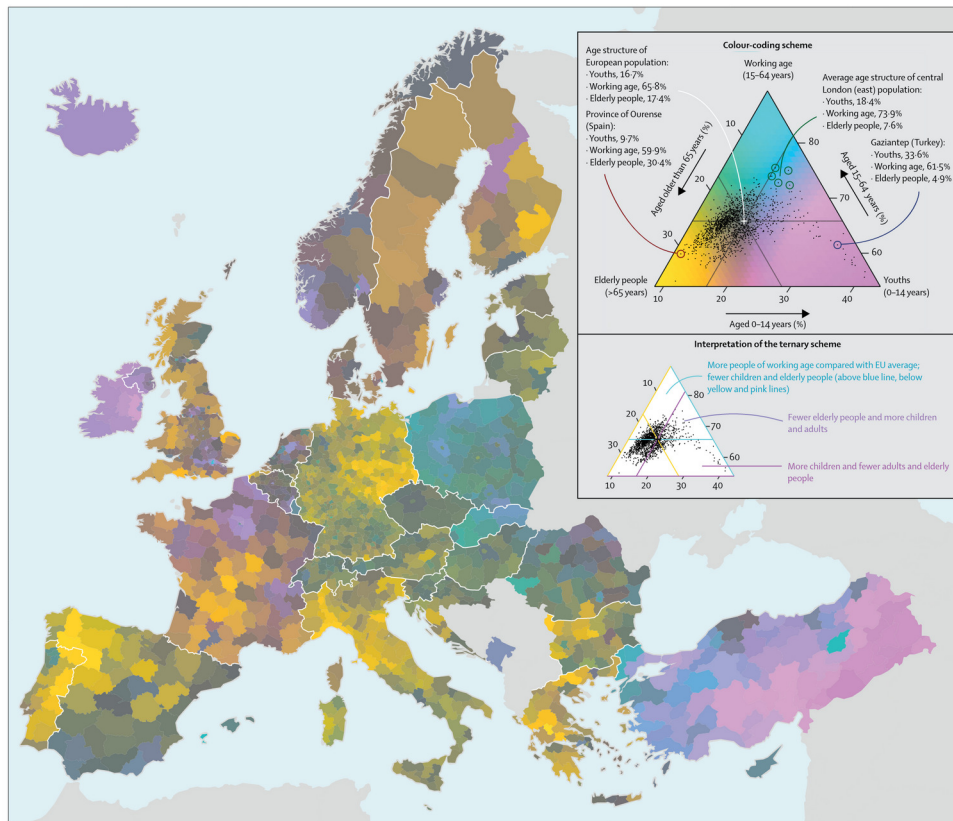

## Testing

- The `survdif` function in [survival](#) compares survival curves using the Fleming-Harrington G-rho family of test. [NADA](#) implements this class of tests for left-censored data.
- The [maxcombo](#) package compares survival curves using the max-combo test, which is often based on the Fleming-Harrington G-rho family of tests and is designed to have higher power than the logrank test in the scenario of non-proportional hazards such as those resulting from delayed treatment effects.
- [clinfun](#) implements a permutation version of the logrank test and a version of the logrank that adjusts for covariates.
- The [exactRankTests](#) implements the shift-algorithm by Streitberg and Roehmel for computing exact conditional p-values and quantiles, possibly for censored data.
- `SurvTest` in the [coin](#) package implements the logrank test reformulated as a linear rank test.
- The [maxstat](#) package performs tests using maximally selected rank statistics.
- The [interval](#) package implements logrank and Wilcoxon type tests for interval-censored data.
- Three generalised logrank tests and a score test for interval-censored data are implemented in the [glrt \(archived\)](#) package.
- [survcomp](#) compares 2 hazard ratios.
- The [TSHRC](#) implements a two stage procedure for comparing hazard functions.
- The [FHtest](#) package offers several tests based on the Fleming-Harrington class for comparing survival curves with right- and interval censored data.
- The [LogrankA \(archived\)](#) package provides a logrank test for which aggregated data can be used as input.
- The short term and long term hazard ratio model for two samples survival data can be found in the [YPmodel](#) package.
- The [controlTest](#) implements a nonparametric two-sample procedure for comparing the median survival time.
- The [survRM2](#) package performs two-sample comparison of the restricted mean survival time
- The [emplik2](#) package permits to compare two samples with censored data using empirical likelihood ratio tests.
- The [KONPsurv](#) package provides powerful nonparametric K-sample tests for right-censored data. The tests are consistent against any differences between the hazard functions of the groups.

**Figure: Colour-coded map of population structures in European Nomenclature of Territorial Units for Statistics 3 regions in 2015**  
Each population composition in the European Nomenclature of Territorial Units for Statistics 3 regions is uniquely colour coded. Colours show direction and magnitude of deviations from the centrepunt, which represents the average age of the European population, and is dark grey. The hue component of a colour encodes the direction of deviation: yellow indicates an elderly population (>65 years), cyan indicates people of working age (15–64 years), and magenta indicates children (0–14 years). Chroma and lightness components signify the distance from the centre ranging from desaturated and dark colours near the centre to vivid and bright colours at the corners. We provide R code to fully reproduce this map.<sup>28</sup>

Figure: Colour-coded map of population composition by region in Europe, 2016. Each population composition in the map is represented by a point. The centrepoint, which represents the average composition of the entire European population, is marked by a black dot. Cyan indicates people of working age (15-64 years), yellow indicates people of young age (0-14 years), and magenta indicates people of elderly age (65+ years). Desaturated and dark colours near the centre to vivid and bright colours at the corners.

## tricolore. A flexible color scale for ternary compositions

Jonas Schöley & Ilya Kashnitsky

CRAN 1.2.0 build: passing License: GPL v3

### What is *tricolore*?

*tricolore* is an R library providing a flexible color scale for the visualization of three-part (ternary) compositions. Its main functionality is to color-code any ternary composition as a mixture of three primary colours and to draw a suitable color-key. *tricolore* flexibly adapts to different visualization challenges via

- *discrete* and *continuous* color support,
- support for unbalanced compositional data via *centering*,
- support for data with very narrow range via *scaling*,
- *hue*, *chroma* and *lightness* options.

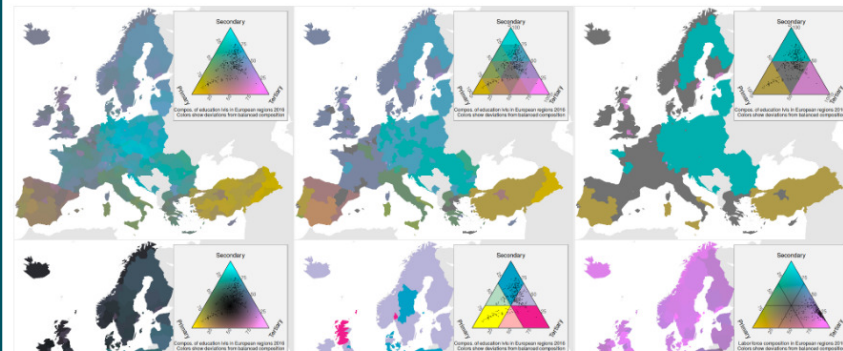

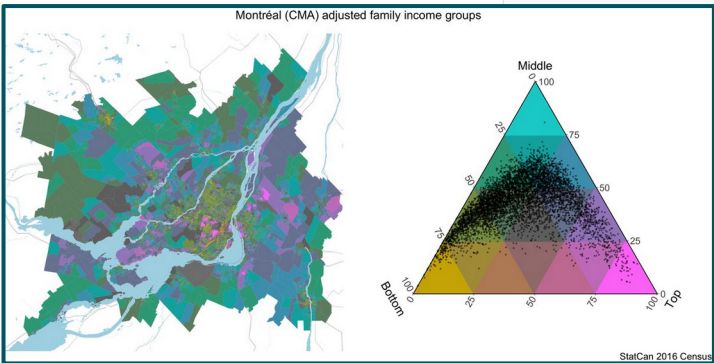

Figure: Colours of population composition in the European Nomenclature of territorial units for statistics regions is uniquely colour coded. Colours show direction and magnitude of deviations from the centrepoint, which represents the average age of the European population, and is dark grey. The hue component of a colour encodes the direction of deviation: yellow indicates an elderly population (>65 years), cyan indicates people of working age (15–64 years), and magenta indicates children (0–14 years). Chroma and lightness components signify the distance from the centre ranging from desaturated and dark colours near the centre to vivid and bright colours at the corners. We provide R code to fully reproduce this map.<sup>10</sup>

Maxi **Kniffka** @MaxiKniffka & Jessica Donzowa @jdonzowa

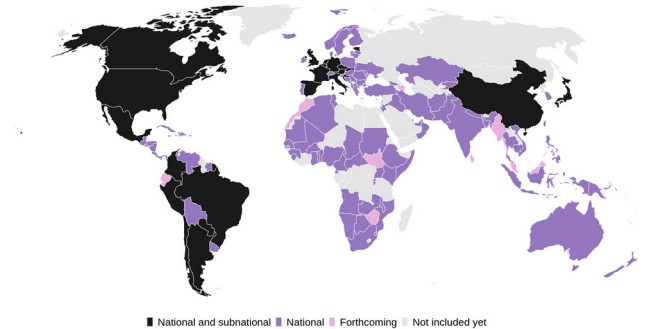

Created a fully reproducible data base of  
age specific COVID-19 statistics.

## Data availability

You can get the most up-to-date data at the [OSF](https://osf.io/mpwjq/) site that we mirror to: <https://osf.io/mpwjq/>.

Here's an overview of global coverage as of now. A country marked as *forthcoming* means we've identified a source, but that collection is pending for one reason or another. Are you from one of the countries not yet in the collection and want to pitch in? Are you interested in adopting collection for one of our time series that has fallen behind? We're in need of more support. Please reach out, if so by emailing us at [coverage-db@demogr.mpg.de](mailto:coverage-db@demogr.mpg.de).
